# 1. General Principles

## 1.1. The Four Horseman of Mechanics

- Length
- Mass
- Time
- Force

So you basically take three of them and solve the 1 left.

## 1.2. US Customary Units

LENGTH	MASS	TIME	FORCE
meter m	kilogram kg	second s	force $\text{kg m s}^{-2}$
foot ft	slug $\text{lb s}^2 \text{ft}^{-1}$	second s	pound lb

Table 1: SI and US Customary (FPS) Units for Mechanics

## 1.3. Gravity

$$F = G \frac{m_1 m_2}{r^2} \quad (1.1)$$

$$F = ma \quad (1.2)$$

In this course, we will use

$$g = 9.81 \text{ m s}^{-2} \quad (2)$$

which happens to be true for Vancouver.

## 1.4. Vector Notation

In this course, vectors are upright bold, and vector magnitudes are italicized bold, while unit vectors are italics with an hat over.

$$\mathbf{A} \text{ has a magnitude of } \mathbf{A} \text{ in direction } \hat{\mathbf{A}}. \quad (3)$$

In manuscript, of course we cannot strike bold, so we use overhead arrow for vectors instead.

## 1.5. Angle Unit

In this course, angles are in degrees.

## 1.6. Drawing Diagrams

- Draw it *big*.
- Draw axis.
- Draw forces and couple moments.

- Do *not* draw moments due to forces.

## 2. Force Vectors

Force, having both magnitude and direction, is a vector. Intuitively, we can apply all kinds of vector operations to forces, as you would learn in MATH 152.

### 2.1. Addition

Use “tip to tail” for triangular method of addition: draw the vectors head to tail, and the resultant vector is the vector from the tail of the first vector to the head of the last vector.

### 2.2. Force Components

$$\mathbf{F} = x\hat{i} + y\hat{j} \quad (4)$$

where  $x, y$  are magnitudes of the force in the  $\hat{i}, \hat{j}$  directions.

Force  $\mathbf{F}$  can be represented as a combination of  $\mathbf{F}_x$  and  $\mathbf{F}_y$

$$\mathbf{F} = \mathbf{F}_x + \mathbf{F}_y \quad (5)$$

or as a polar coordinate of angle  $\theta = \arctan\left(\frac{F_y}{F_x}\right)$  and magnitude  $F$

$$\mathbf{F} = F(\cos(\theta)\hat{i} + \sin(\theta)\hat{j}). \quad (6)$$

To generalize it, we can write it as

$$\mathbf{F} = F_x\hat{i} + F_y\hat{j} \quad (7.1)$$

$$= F(\cos(\theta)\hat{i} + \sin(\theta)\hat{j}) \quad (7.2)$$

where  $\hat{i}, \hat{j}$  are unit vectors in the  $x, y$  directions. This is the Cartesian form of a vector.

For a force with 2 dimensions, we call it a coplanar force.

Sometimes, non-linear equations arise from problems involving forces. Gladly use math solvers for those.

### 2.3. Unit Vector

To disregard magnitude and only focus on direction, we use unit vector, which we divide a vector by its magnitude,  $\hat{u} = \frac{\mathbf{A}}{A}$ .

### 2.4. 3D Forces

Forces in 3D are  $\mathbf{F} = F_x\hat{i} + F_y\hat{j} + F_z\hat{k}$ , with their magnitudes being  $F = \sqrt{F_x^2 + F_y^2 + F_z^2}$ .

To determine orientation of the axis, we use the right-hand rule: make a thumb up using your right hand, the side of the curling fingers is  $x$ , the arm is  $y$ , and the thumb is  $z$ .

#### 2.4.1. Direction of Cartesian Vector

The direction of a Cartesian vector is the angles between the vector and the **positive** axis.  $\alpha, \beta, \gamma$  each corresponds to the angle from the positive  $x, y, z$  axis.

$$\cos(\alpha) = \frac{F_x}{F} \quad (8.1)$$

$$\cos(\beta) = \frac{F_y}{F} \quad (8.2)$$

$$\cos(\gamma) = \frac{F_z}{F} \quad (8.3)$$

Therefore,

$$\hat{\mathbf{u}} = \cos(\alpha)\hat{\mathbf{i}} + \cos(\beta)\hat{\mathbf{j}} + \cos(\gamma)\hat{\mathbf{k}} \quad (9)$$

and

$$\mathbf{F} = F\hat{\mathbf{u}} \quad (10.1)$$

$$= F(\cos(\alpha)\hat{\mathbf{i}} + \cos(\beta)\hat{\mathbf{j}} + \cos(\gamma)\hat{\mathbf{k}}) \quad (10.2)$$

The directions satisfy  $-180^\circ < \alpha, \beta, \gamma < 180^\circ$  and have identity

$$\cos^2(\alpha) + \cos^2(\beta) + \cos^2(\gamma) = 1. \quad (11)$$

#### 2.4.2. Determining 3D Force Components

Figure 1: A Cartesian Vector

With magnitude  $F$  and angles from the positive  $z$ -axis  $\varphi$  and from the positive  $x$ -axis  $\theta$ , we can determine the force components by first solving for  $F_z$ , then  $F_{xy}$  followed by  $F_x$  and  $F_y$ .

$$F_z = F \cos(\varphi) \quad (12.1)$$

$$F_{xy} = F \sin(\varphi) \quad (12.2)$$

$$F_x = F_{xy} \cos(\theta) \quad (12.3)$$

$$F_y = F_{xy} \sin(\theta) \quad (12.4)$$

Or instead, given 2 ( $\beta, \gamma$ ) of the 3 Cartesian angles, we can determine the force by

$$\cos(\alpha) = \sqrt{1 - \cos^2(\beta) - \cos^2(\gamma)} \quad (13.1)$$

$$\mathbf{F} = F(\cos(\alpha)\hat{\mathbf{i}} + \cos(\beta)\hat{\mathbf{j}} + \cos(\gamma)\hat{\mathbf{k}}). \quad (13.2)$$

## 2.5. Position Vectors

Position vectors are vectors that describe the position of a point in space relative to a reference point.

As obvious, we need 3 coordinates to locate a point in 3D space. Point  $P(x, y, z)$  has position vector  $\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$  relative to the origin.

Note that the position vector does not always come from the origin, it can be relative to arbitrary points. Given  $A(x_A, y_A, z_A)$  and  $B(x_B, y_B, z_B)$ , the position vector of  $B$  relative to  $A$  is

$$\mathbf{r} = (x_B - x_A)\hat{\mathbf{i}} + (y_B - y_A)\hat{\mathbf{j}} + (z_B - z_A)\hat{\mathbf{k}}. \quad (14)$$

Connecting to unit vectors,  $\mathbf{u} = \frac{\mathbf{F}}{F}$ ,

$$\mathbf{F} = F\mathbf{u} = F\frac{\mathbf{r}}{r}. \quad (15)$$

To simplify calculation, let  $X = \frac{F}{r}$ ,

$$\mathbf{F} = X\mathbf{r} \quad (16.1)$$

$$F = Xr. \quad (16.2)$$

## 2.6. Vector Operations

Mostly taught in MATH 152, but here again anyways.

### 2.6.1. Dot Product & Angle Between Vectors

$$\mathbf{A} \cdot \mathbf{B} = AB \cos(\theta) \quad (17.1)$$

$$= A_x B_x + A_y B_y + A_z B_z \quad (17.2)$$

### 2.6.2. Parallel & Perpendicular Components

Two vectors are parallel if their cross product is a zero vector, and perpendicular if their dot product is zero.

Given a vector  $\mathbf{A}$ , its parallel component is

$$\mathbf{A}_{\parallel} = (\mathbf{A} \cdot \hat{\mathbf{u}})\hat{\mathbf{u}} \quad (18)$$

and its perpendicular component is

$$\mathbf{A}_{\perp} = \mathbf{A} - \mathbf{A}_{\parallel}. \quad (19)$$

### 2.6.3. Projection

The projection of  $\mathbf{A}$  onto  $\mathbf{B}$  is

$$\mathbf{A}_{\text{proj on B}} = (\mathbf{A} \cdot \hat{\mathbf{u}}_B) \hat{\mathbf{u}}_B. \quad (20)$$

Note the similarity to the parallel component formula.

### 3. Equilibrium of a Particle

This section only concerns static equilibrium, where the particle is at rest. In other words,

$$\sum \mathbf{F} = 0. \quad (21)$$

#### 3.1. Free-Body Diagram

To draw a free-body diagram,

1. Draw a labeled right-hand coordinate system.
2. Draw outlined shape.
3. Show all forces.

Since this is static equilibrium, account for *active* and *reactive* forces.

4. Identify and label each force.

#### 3.2. Coplanar Force Systems

On a 2D plane, forces can be resolved into  $x, y$  components.

$$\sum F_x = 0 \quad (22.1)$$

$$\sum F_y = 0. \quad (22.2)$$

#### 3.3. 3D Force Systems

Forces in 3D can be resolved into  $x, y, z$  components.

$$\sum F_x = 0 \quad (23.1)$$

$$\sum F_y = 0 \quad (23.2)$$

$$\sum F_z = 0. \quad (23.3)$$

Be very careful with the signs of the forces.

#### 3.4. Solving Equilibrium Problems

With multiple forces and their direction vectors (*not unit vectors*)  $\mathbf{r}$ ,

$$\mathbf{F} = r\mathbf{X} \text{ or } Y \text{ or } Z... \quad (24)$$

where  $X, Y, Z... = \frac{\mathbf{F}}{r}$ . Solving for  $X, Y, Z$  gives the forces. To solve a typical  $X, Y, Z$  system, we can use the `rref` function on a matrix of the coefficients in the equations and their RHS. More in MATH 152.

Why don't we directly compute the values? Try and see for yourself, you will come back to the  $X, Y, Z$ 's.

A sanity check would be to ensure that the forces are on the same magnitude as the original forces, and are in somewhat canceling directions.

As always, check angles and signs. Forces project to the negative axis have  $\alpha, \beta, \gamma > 90^\circ$ .

## 4. Force System Resultants

Forces can produce different results.

**Force** Causes translation of a body.

**Moment/Torque** Causes rotation of a body.

Translation happens on the same plane as the forces, while rotation happens perpendicular to the plane.

In this course of statics, we study not the translations or rotations, but the *tendencies* for the bodies to act so.

These results combined are called the force system resultants.

### 4.1. Moment of a Force

Intuitively, magnitude of the moment of a force  $\mathbf{F}$  about point  $O$  is

$$M_O = Fd \quad (25)$$

where  $d$  is the perpendicular distance from  $O$  to the line of action of  $\mathbf{F}$ .

Multiple moments? Just sum them up.

By convention (curl of fingers in the Right Hand Rule), positive moments point to the positive  $z$  axis, counterclockwise.

To understand rotation in a simple way, think of (or actually do) opening a door at different points in different directions.

Now, be reminded that the cross product of two vectors produces a vector perpendicular to the plane of the two vectors.

#### 4.1.1. Cross Product

Samely, more in MATH 152.

$$\mathbf{A} \times \mathbf{B} = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ A_x & A_y & A_z \\ B_x & B_y & B_z \end{vmatrix} \quad (26.1)$$

$$= (A_y B_z - A_z B_y)\hat{i} - (A_x B_z - A_z B_x)\hat{j} + (A_x B_y - A_y B_x)\hat{k} \quad (26.2)$$

which is perpendicular to both  $\mathbf{A}$  and  $\mathbf{B}$ .

And it is non-commutative.

$$\mathbf{C} = \mathbf{A} \times \mathbf{B} \quad (27.1)$$

$$-\mathbf{C} = \mathbf{B} \times \mathbf{A} \quad (27.2)$$

It is mandated that we show construction of the determinant in exams even if we use calculators.

## 4.2. Vector Formulation of Moment

$$\mathbf{M}_O = \mathbf{r} \times \mathbf{F} \quad (28)$$

where  $\mathbf{r}$  is the position vector of the point of application of  $\mathbf{F}$  relative to  $O$ , in other words, *any* vector from  $O$  to the line of action of  $\mathbf{F}$ .

The magnitude of  $M_O$  is then

$$M_O = rF \sin(\theta) \quad (29.1)$$

$$= Fd \quad (29.2)$$

$$\mathbf{M}_{\text{axis}} = \mathbf{u}_{a_x} \times (\mathbf{r} \times \mathbf{F}) \quad (29.3)$$

$$= \mathbf{u}_{a_x} \times \mathbf{M}_O \text{ (this can commute)}. \quad (29.4)$$

Using our recent knowledge of Cartesian vectors and cross products, we can write the moment as

$$\mathbf{M}_O = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ r_x & r_y & r_z \\ F_x & F_y & F_z \end{vmatrix} \quad (30)$$

## 4.3. Moment of a Couple

**Couple** A pair of forces of equal magnitude, opposite direction, and parallel lines of action.

$$\mathbf{M}_{\text{couple}} = \mathbf{r}_A \times -\mathbf{F} + \mathbf{r}_B \times \mathbf{F} \quad (31.1)$$

$$\mathbf{M}_{\text{couple}} = Fd \quad (31.2)$$

where  $d$  is the perpendicular distance between the lines of action of the forces.

The moment of a couple is independent of the point about which it is taken it is a *free vector*.

The moment of a couple is the same about any point.

## 4.4. Equivalent Systems

Two systems are equivalent if they produce the same external effects on a body.

To ‘shift’ a force, we can make it a couple by adding a pair of force of equal magnitude, of opposite direction, parallel to the original force at the desired location. Then, add the couple moment somewhere and cancel the original force.

## 4.5. Couple of Moments

$$\mathbf{M}_{\text{couple}} = \mathbf{M}_A + \mathbf{M}_B. \quad (32)$$

## 4.6. Simplification of Force Systems

To simplify a force system, we can

1. Move forces to a common point.

2. Place the moments of couples at the common point.
3. Replace the forces with their resultant.

**Concurrent Forces** Lines of forces that pass through a common point. They produce no moment about that point.

**Coplanar Forces** Forces that lie in the same plane.

**Parallel Forces** Forces that have parallel lines of action.

A parallel force system can be simplified by replacing the forces with a single resultant force and a single resultant moment. It can then be further simplified by moving the resultant force to the point of application of the resultant moment.

$$\mathbf{F}_R \text{ and } \mathbf{M}_O \text{ at } O = \mathbf{F}_R \text{ with distance } \frac{\mathbf{M}_O}{\mathbf{F}_R}. \quad (33)$$

#### 4.6.1. Reduction to a Wrench

Given arbitrary forces and moments, we can reduce them to a single force and a single moment.

1. Regard the resultant force as a baseline, moments parallel to the force can be eliminated by moving the force to a distance  $d = \mathbf{M}_\perp / \mathbf{F}_R$ .
2. Move the parallel moment to the resultant force.

When solving for the resultant force, first setup an imaginary point  $P$  as our resultant force point, then solve for the resultant force and moment about  $P$ . Make use of the fact that the resultant moment must be parallel to the resultant force.

## 5. Equilibrium of a Rigid Body

**Internal Forces** Forces that hold the particles of a body together.

**External Forces** Forces that act on the body as a whole.

For equilibrium, we do not consider internal forces, because they always occur in pairs and cancel each other out.

In equilibrium, the sum of the forces and moments acting on a rigid body is zero, in other words, vanish.

$$\sum \mathbf{F} = 0 \quad (34.1)$$

$$\sum M_O = 0. \quad (34.2)$$

It does not matter where the point  $O$  is.

When a body is in equilibrium, it is in both translational and rotational equilibrium. Typically, it is supported by something, and the forces and moments include the reactions of the supports. If a support restricts translation, it produces a reaction force, and if it restricts rotation, it produces a reaction moment.

### 5.1. Types of Supports

- Roller: Restricts translation in one direction.
- Ball and socket: Restricts translation in all directions.
- Single journal bearing: Only allows translation in one direction and rotation about that direction.
- Double journal bearing: Only allows translation in two directions, *does not restrict rotation directly, but does through restricting translation, which means **no reactant moment***. The same for other journal bearings.
- Single journal bearing with square shaft: Only allows translation in one direction.
- Single thrust bearing: Only allows rotation in one direction.
- Single smooth pin: Only allows rotation about the pin.
- Single hinge: Only allows rotation about the hinge.
- Fixed support: Restricts translation and rotation in all directions.

The translation and rotation restricted correspond to the reaction forces and moments produced by the support.

## 6. Friction

**Friction** Force of resistance acting on a body that prevents or retards slipping of body or surface with which it is in contact.

**Fluid friction** Contacting surfaces separated by film of fluid (won't consider here).

**Dry friction** No lubricating fluid between surfaces of body in contact.

**Coefficient of static friction ( $\mu_s$ )** the magnitude of friction per normal force when a body is static.

The cause of dry friction is the rough surfaces in contact. There are little, microscopic bumps: 'teeth' and 'valleys', which they clutch into each other to hinder movement. Since they have to 'clutch in', there is a component of the resultant force perpendicular to the contact surface, the normal force  $N$ . Of course, then there is the friction  $F$ , tangent to the contact surface and opposite to the (intended) movement.

Figure 2: Dry friction

Look at the example above. Assume the block is in equilibrium, we can determine where  $N$  is acting, point  $O$ , by considering moments.

$$Wx = Ph \quad (35.1)$$

$$x = \frac{Ph}{W}. \quad (35.2)$$

Other than slip or not slip, the body can also tip!

**Impending motion** No motion but friction is at its maximum, any larger propelling force will cause the body to slip. Only when at impending motion,

$$F_s = \mu_s N. \quad (36)$$

**Angle of static friction** The angle between the resultant force by friction and the normal force and the normal force.

It is important to notice that, only when the body is *about* to slip, the above formula is true. In other cases,  $F_s$  depends on the propelling force.

**Kinetic friction** Friction when a body is in motion, typically *smaller* than its static friction.

**Coefficient of kinetic friction ( $\mu_k$ )** Similar to  $\mu_s$  but for kinetic friction.

When there are multiple ways a body can slip, calculate the  $P$  required for each case, then choose the one with the *smallest*  $P$ .

When using  $F = \mu N$ , the direction drawn must be correct! Otherwise, no, it can be wrong and we correct it later according to the sign.

## 7. Kinematics of a Particle

From now on, we need to consider motion of bodies, which would require a bit of calculus.

**Velocity** Rate of change of position with respect to time.

$$v = \frac{ds}{dt} \quad (37)$$

**Acceleration** Rate of change of velocity with respect to time.

$$a = \frac{dv}{dt} = \frac{d^2s}{dt^2} \quad (38)$$

For their instantaneous values, take  $\lim_{\Delta t \rightarrow 0}$ .

Given the definition of acceleration and velocity, we can get that

$$a \, ds = ds \frac{dv}{dt} = \frac{ds}{dt} dv = v \, dv. \quad (39)$$

If acceleration is known as a function of time, the relationship above can help us determine the velocity.

A particle has position vector  $\mathbf{r} = (x\mathbf{i}, y\mathbf{j}, z\mathbf{k})$ , and its velocity is the first derivative of position regarding time,  $\mathbf{v} = \frac{d\mathbf{r}}{dt} = \left( \frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt} \right)$ .

These differentiation with respect to time are notated using overdot,  $\dot{x} = \frac{dx}{dt}$ .

Acceleration is then the derivation of velocity, or the second degree derivation of position:  $\mathbf{a} = \frac{d\mathbf{v}}{dt} = \frac{d^2\mathbf{r}}{dt^2} = \left( \frac{dv_x}{dt}, \frac{dv_y}{dt}, \frac{dv_z}{dt} \right)$ .

### 7.1. Projectile Motion

Projectile or trajectory motion, is something being thrown into the air and affected by gravity. We ignore air resistance for now.

Velocity on the x-axis will not change, as there is no force acting in that direction,

$$a_x = 0 \quad (40.1)$$

$$v_x = (v_0)_x. \quad (40.2)$$

Velocity on the y-axis will change according to the gravitational acceleration,  $g = 9.81 \, \text{m s}^{-2}$ ,

$$a_y = -g \quad (41.1)$$

$$v_y = (v_0)_y - gt \quad (41.2)$$

$$y = y_0 + (v_0)_y t - \frac{1}{2}gt^2, \quad (41.3)$$

$$v_y^2 = (v_0)_y^2 - 2g(y - y_0) \quad (41.4)$$

And generally,

$$v^2 = v_0^2 + 2a(s - s_0). \quad (42)$$

Now we can describe a trajectory motion as a function for  $y$  of  $x$ :

$$y(x) = a(x - x_0)^2 + b(x - x_0) + y_0 \quad (43.1)$$

$$\text{where } a = -\frac{g}{2v_0^2 \cos^2(\theta_0)} \quad (43.2)$$

$$b = \tan(\theta_0). \quad (43.3)$$

## 8. Kinetics of a Particle: Force and Acceleration

A particle path can be seen comprising of differential arc of a circle with radius,  $\rho$ , known as the radius of curvature, and a center  $O'$ , the center of curvature.

In limit of a straight path,  $\rho \rightarrow \infty$ .

In 2D space, for a particle with path  $f(x)$ ,

$$\rho = \frac{\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{\frac{3}{2}}}{\frac{d^2y}{dx^2}}. \quad (44)$$

Velocity of the particle, in such cases, is

$$v = ds dt = \dot{s} \quad (45.1)$$

$$\mathbf{v} = v\mathbf{u}_t. \quad (45.2)$$

There is no normal component to it.

Acceleration is then

$$\mathbf{a} = \frac{dv}{dt} \quad (46.1)$$

$$= \frac{d}{dt}v\mathbf{u}_t \quad (46.2)$$

$$= \dot{v}\mathbf{u}_t + v\dot{\mathbf{u}}_t \quad (46.3)$$

$$\dot{\mathbf{u}}_t = \frac{d}{d\theta}\mathbf{u}_n \quad (46.4)$$

$$= \dot{\theta}\mathbf{u}_n \quad (46.5)$$

$$\dot{\theta} = \frac{v}{\rho} \quad (46.6)$$

$$\mathbf{a} = \dot{v}\mathbf{u}_t + \frac{v^2}{\rho}\mathbf{u}_n \quad (46.7)$$

$$a = \|\mathbf{a}\|. \quad (46.8)$$

In a straight-line motion,  $\rho \rightarrow \infty$ ,  $a_n = 0$ . In a constant-speed motion,  $\dot{v} = 0$ ,  $a_t = 0$ . We can see that the tangential acceleration represents the change in magnitude of velocity, and the normal acceleration represents the change in direction of velocity.

### 8.1. Polar and Cylindrical Coordinates

Instead of  $x, y$ , a polar coordinate system holds  $r \wedge \theta$ , which  $r$  is the distance from the origin and  $\theta$  is the angle from the positive x-axis. The position vector would be  $\mathbf{r} = r\mathbf{u}_r$ .

For an object which position is described by  $\mathbf{r}$ ,

$$\mathbf{v} = \dot{\mathbf{r}} \quad (47.1)$$

$$= (\dot{r}\mathbf{u}_r) \quad (47.2)$$

$$= \dot{r}\mathbf{u}_r + r\dot{\mathbf{u}}_r, \dot{\mathbf{u}}_r = \dot{\theta}\mathbf{u}_\theta, \quad (47.3)$$

$$\mathbf{v} = v_r\mathbf{u}_r + v_\theta\mathbf{u}_\theta. \quad (47.4)$$

Separating the velocity,

$$v_r = \dot{r} \quad (48.1)$$

$$v_\theta = r\dot{\theta} \quad (48.2)$$

$$\mathbf{v}_r = \dot{r}\mathbf{u}_r \quad (48.3)$$

$$\mathbf{v}_\theta = (r\dot{\theta})\mathbf{u}_\theta. \quad (48.4)$$

And knowing that

$$\dot{\mathbf{u}}_\theta = -\dot{\theta}\mathbf{u}_r \quad (49.1)$$

$$\dot{\mathbf{u}}_r = \dot{\theta}\mathbf{u}_\theta. \quad (49.2)$$

We have

$$\mathbf{a} = (\ddot{r} - r\dot{\theta}^2)\mathbf{u}_r + (r\ddot{\theta} + r\dot{r}\dot{\theta})\mathbf{u}_\theta \quad (50.1)$$

$$a_r = \ddot{r} - r\dot{\theta}^2 \quad (50.2)$$

$$a_\theta = r\ddot{\theta} + 2\dot{r}\dot{\theta}. \quad (50.3)$$

Note that usually  $\theta$  is a functions of time, so when deriving functions of  $\theta$ , e.g.  $r$ , we should apply chain rule properly.

## Definitions

**Force**° Causes translation of a body.

**Moment/Torque**° Causes rotation of a body.

**Couple**° A pair of forces of equal magnitude, opposite direction, and parallel lines of action.

**Concurrent Forces**° Lines of forces that pass through a common point. They produce no moment about that point.

**Coplanar Forces**° Forces that lie in the same plane.

**Parallel Forces**° Forces that have parallel lines of action.

**Internal Forces**° Forces that hold the particles of a body together.

**External Forces**° Forces that act on the body as a whole.

**Friction**° Force of resistance acting on a body that prevents or retards slipping of body or surface with which it is in contact.

**Fluid friction**° Contacting surfaces separated by film of fluid (won't consider here).

**Dry friction**° No lubricating fluid between surfaces of body in contact.

**Coefficient of static friction ( $\mu_s$ )**° the magnitude of friction per normal force when a body is static.

**Impending motion**° No motion but friction is at its maximum, any larger propelling force will cause the body to slip. Only when at impending motion,

$$F_s = \mu_s N. \quad (51)$$

**Angle of static friction**° The angle between the resultant force by friction and the normal force and the normal force.

**Kinetic friction**° Friction when a body is in motion, typically *smaller* than its static friction.

**Coefficient of kinetic friction ( $\mu_k$ )**° Similar to  $\mu_s$  but for kinetic friction.

**Velocity**° Rate of change of position with respect to time.

$$v = \frac{ds}{dt} \quad (52)$$

**Acceleration**° Rate of change of velocity with respect to time.

$$a = \frac{dv}{dt} = \frac{d^2s}{dt^2} \quad (53)$$
